Herbicide Efficacy in No-Trill Parming Systems in Southern NSW -2010-

Introduction

Variable rainfall patterns over the past ten years in southern NSW have prompted the rapid adoption of no-till, stubble retained farming systems to maximise crop water use efficiency. Despite the many benefits of this system, the efficacy of pre-emergent herbicides remains one of the major concerns for growers and advisers who have adopted, or are considering adoption, of the system.

Pre-emergent herbicides play an important role in integrated weed management programs as they allow for rotation away from high risk Group A and B herbicides. However, poor efficacy of pre-emergent herbicides can still result in the rapid development of herbicide resistance, as has occurred with trifluralin resistance that is common in southern Australia.

The efficacy of many pre-emergent herbicides relies on the ability to incorporate them into the soil at sowing. In no-till systems, however, knife points and to a greater extent, disc openers, provide minimal soil disturbance at sowing to limit moisture loss, but which consequently also limit herbicide incorporation. Retained stubble also acts as a physical barrier to herbicide/soil contact. This issue is further confounded where livestock are included in the system, with stubble laid flat from trampling providing a physical barrier to herbicide uptake. Effective pre-emergent herbicide strategies are required to ensure the future sustainability of both herbicides and no-till farming systems.

Objectives

To identify the most effective pre-emergent herbicide strategies for use in no-till, stubble retained farming systems in southern NSW as part of an integrated weed management program.

Methodology

Three trial sites were located across southern NSW near Grenfell, Wagga Wagga and Lockhart in commercial paddocks currently utilising a no-till, stubble retained system. In each paddock, 11 herbicide treatments (Table 1) were applied by AgriTech pre-sowing* using a 6-metre boom in large, randomised plots, replicated three times for both disc and tyne sowing systems (see trial plan in Appendix).

Commercial seeders (Table 2) were used to sow the plots with wheat immediately after herbicide application (incorporated by sowing), using typical sowing speeds to ensure adequate soil throw and accurate seed placement.

| Table 1 - Herbicide treatments, Herbicide Efficacy Trials 2010 | | | | | | | | |
|--|--------------------|-----------------------|--|--|--|--|--|--|
| Herbicides | Rates/ha | Indicative cost \$/ha | | | | | | |
| Triflur X ¹ | 1.5L | \$8 | | | | | | |
| Triflur X ¹ | 3L | \$16 | | | | | | |
| Boxer Gold ¹ | 2.5L | \$41 | | | | | | |
| Boxer Gold ¹ + Avadex Xtra | 2.5L + 1.6L | \$63 | | | | | | |
| Sakura ² | 118g | na | | | | | | |
| Sakura² + Avadex Xtra | 118g + 1.6L | na | | | | | | |
| Triflur X1 + Avadex Xtra | 1.5L + 1.6L | \$30 | | | | | | |
| Triflur X1 + Avadex Xtra | 2L + 2L | \$38 | | | | | | |
| Triflur X1 + Logran | 1.5L + 35g | \$11 | | | | | | |
| Triflur X ¹ + Logran + Dual Gold ³ | 1.5L + 35g + 500mL | \$21 | | | | | | |
| Triflur X ¹ + Logran + Diuron ³ | 1.5L + 35g + 500g | \$17 | | | | | | |

*Dual Gold was applied post sowing, pre-emergent at the Wagga Wagga site.

¹not registered for IBS with disc seeders; ²registration pending (due 2011); ³not registered for IBS in wheat in NSW

Methodology cont.

AgriTech applying pre-emergent herbicide treatments at the Downside trial, April 2010

Monitoring

Intensive monitoring was undertaken by AgriTech throughout the season to assess herbicide efficacy and crop safety with assessments, where applicable, including:

- crop establishment plants per metre row, adjusted for row spacing = plants per metre²
- crop vigour visual assessment where 1=poor crop vigour, 9=high crop vigour
- weed counts plant numbers in a strip or quadrat, depending on distribution within plot
- weed control visual assessment relative to untreated buffers
- panicle counts panicle numbers in a quadrat
- yield using a small plot harvester

Statistical analyses of all assessments were undertaken by AgriTech using analysis of variance and factorial analysis of variance.

Site selection

Although all trial sites were selected on the basis that they were used in no-till farming systems, each site was also selected based on expected differences in weed spectrum that are typical of the region.

The Wagga Wagga site had the heaviest weed burden, with very high populations of annual ryegrass (Lolium rigidum). The Grenfell site also had high populations of annual ryegrass, while the Lockhart site had low populations of both annual ryegrass and wild oats (Avena fatua).

Results

Different outcomes relating to herbicide efficacy were achieved at each site due to variations in weed density, soil moisture and stubble loads. However in relation to disc versus type seeding comparisons, the type seeder produced consistently better establishment and early crop vigour at all sites. Site specific results are as follows:

Grenfell

- Co-operators: Duncan Lander (disc) and Rob Johnson (tyne)
- Sowing date: 20th May 2010
- Variety: Livingston
- Stubble cover: 80% (wheat stubble)
- 2010 rainfall: 1015mm (Bureau of Meteorology)
- **Site conditions:** Livingston wheat was sown into moist soil and a thick residue of stubble retained from previous wheat crops. Following establishment, approximately 50mm of rain fell onto an already full profile, which remained wet for the entire season. 1015mm of rainfall was measured for the area in 2010, with 650mm falling between September and December. The wet conditions had a major bearing upon outcomes from this trial, particularly the disc treatments which suffered from poor establishment and severe herbicide damage.

Disc seeding into stubble with low to moderate ryegrass numbers at the Grenfell trial, May 2010

• **Establishment:** Plant numbers were significantly higher in the tyne compared with the disc (80 vs 30 plants/m² respectively, P<0.05 - Figure 1). Crop vigour was also better in the tyne treatments (Figure 2), which remained the case through the season. As the soil became wetter during winter, the disc area was unable to recover its vigour due to a range of factors including herbicide damage, yellow leaf spot, nitrogen deficiency and waterlogging.

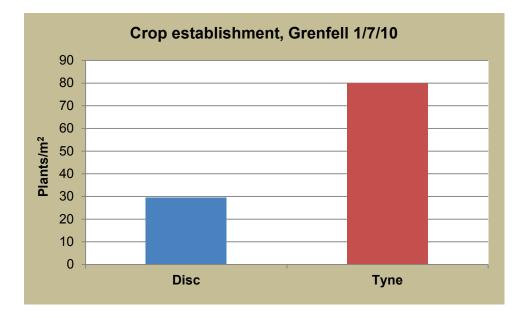

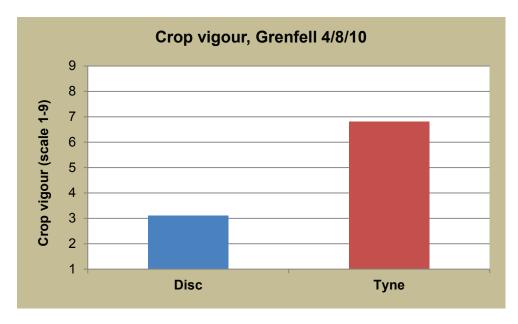

Figure 2 - Crop vigour disc versus tyne, Grenfell (LSD P<0.05 = 0.7)

• Weed control: Low to moderate ryegrass numbers were present at establishment. Although there were no differences in weed control between the disc and tyne systems (Figure 3), there were differences in efficacy between herbicide treatments. Compared with 1.5L/ha trifluralin, the Sakura treatments and Boxer Gold + Avadex Xtra gave significantly better ryegrass control (P<0.05 - Figure 4). Late ryegrass germinations and low crop competition meant the trial became heavily infested and was spray fallowed in October to prevent seed set.

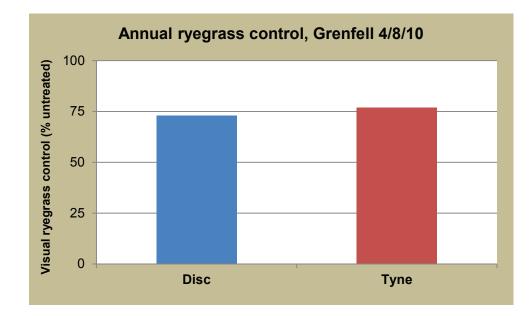

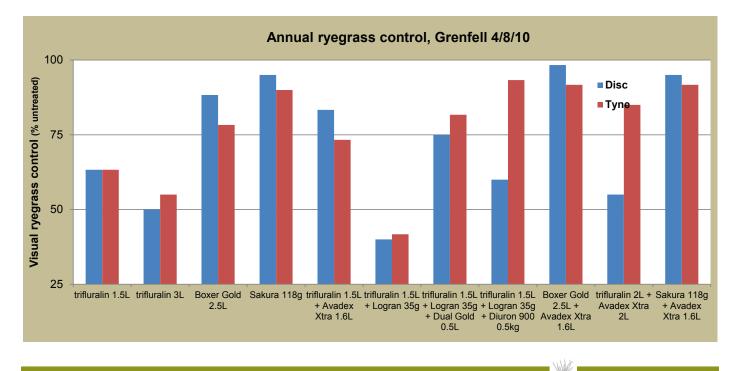

Figure 3 - Weed control disc versus tyne, Grenfell (LSD P<0.05 = 11.8)

Figure 4 - Weed control herbicide comparison, Grenfell (LSD P<0.05 = 39)

• **Crop safety:** Herbicide damage in the disc areas was particularly evident at this site, with the majority of herbicide treatments causing significantly more damage to crop vigour than 1.5L/ha trifluralin (P<0.05 - Figure 5). Damage was also evident in some of the tyne treatments, although the symptoms were only temporary. Yield estimates taken prior to spray fallowing showed the disc treatments to potentially average 0.36t/ha and the tyne treatments 1.0t/ha, with a range across all treatments of 0.15 to 1.37t/ha depending on herbicide, seeding system and weed control.

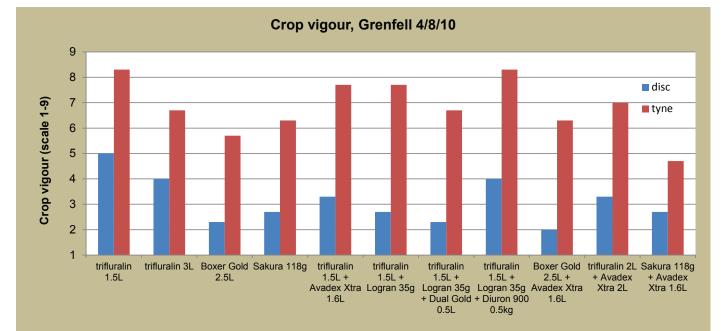

Figure 5 - Crop vigour herbicide comparison, Grenfell (LSD P<0.05 = 2.2)

Pre-emergent herbicides caused significant crop damage to the disc treatments (left) under very wet conditions at the Grenfell trial, July 2010

Lockhart

- Co-operators: Chug Kennedy (disc) and Brent Alexander (tyne)
- Sowing date: 14th May 2010
- Variety: Lincoln
- Stubble cover: 10-60% (burnt wheat stubble)
- 2010 rainfall: 945mm (Bureau of Meteorology)
- **Site conditions:** Lincoln wheat was sown mid-May into dry conditions and patchy stubble cover from an uneven burn to remove header trails. Very low ryegrass and wild oat numbers meant the trial could be retained through to harvest, allowing a valid comparison of disc and tyne systems in the relative absence of weeds.
- **Emergence:** Plant numbers were significantly higher in the tyne compared with the disc (120 vs 80 plants/m² respectively, P<0.05 Figure 6), with disc emergence potentially affected by the presence of stubble remaining across the rows after sowing (inter-row sowing or sowing in the direction of stubble may have countered this). Greater early vigour by the tyne became less apparent as the season progressed (Figure 7).

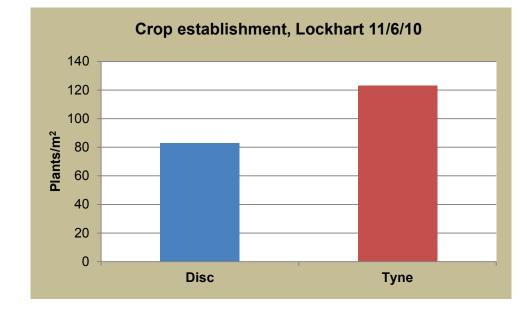

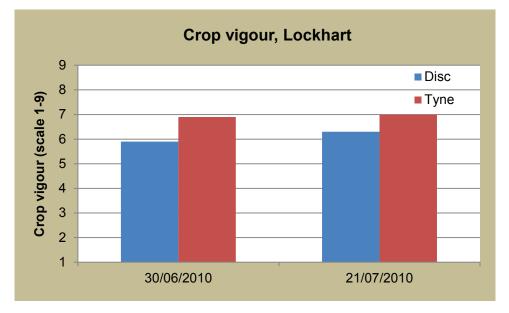

Figure 6 - Crop establishment disc versus tyne, Lockhart (LSD P<0.05 = 7)

- Weed control: Very low weed numbers with uneven distribution across the trial prevented meaningful weed control data being collected.
- Crop safety: Conditions remained dry for approximately two weeks after the trial was established which reduced damage to the emerging crop from residual herbicides. While no herbicide caused crop damage in the tyne treatments, crop safety was compromised with 3L/ha trifluralin in the disc area. Compared with 1.5L/ha trifluralin, the higher rate significantly reduced crop vigour (P<0.05 - Figure 8) and resulted in a significant yield reduction of 13% (Figure 9).

Figure 8 - Crop vigour herbicide comparison, Lockhart (LSD P<0.05 = 0.9)

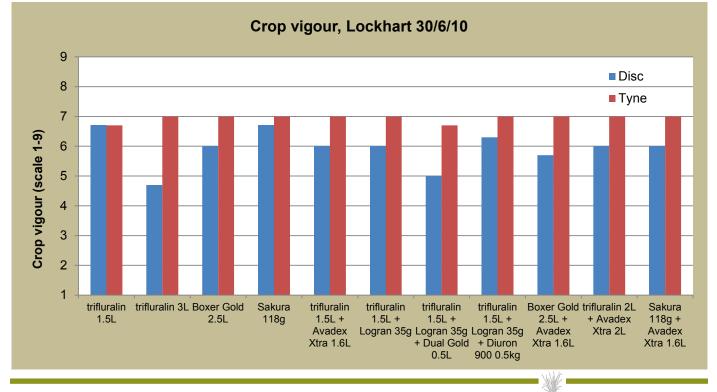

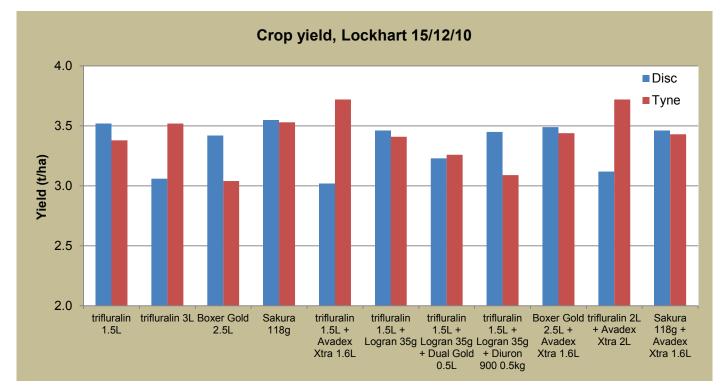

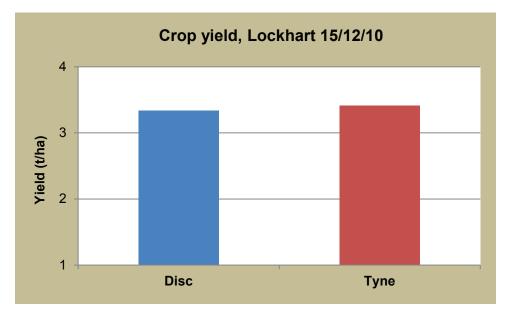

Figure 9 - Crop yield herbicide comparison, Lockhart (LSD P < 0.05 = 0.4)

• Yield: There were no significant yield differences between the disc and tyne treatments (P>0.05 - Figure 10). This was a reflection of the drier nature of the site and subsequent improved crop safety with pre-emergent herbicides.

Figure 10 - Crop yield disc versus tyne, Lockhart (LSD P<0.05 = 0.12)

Wagga Wagga

- Co-operators: John & Brendan Pattison (disc) and Ben Beck (tyne)
- Sowing date: 13th April 2010
- Variety: Wedgetail
- Stubble cover: 50% (wheat stubble)
- 2010 rainfall: 966mm (Wagga Wagga Agricultural Institute, Bureau of Meteorology)
- Site conditions: Wedgetail wheat was sown early into good moisture and 50% stubble cover. Very high ryegrass numbers (up to 190 plants/m²) with low crop competition due to early locust damage represented an extreme scenario to test pre-emergent herbicide efficacy. The trial was spray fallowed in October to prevent weed seed set.

Tyne seeding into stubble with very high ryegrass numbers at the Wagga Wagga trial, April 2010

• **Emergence:** Plant numbers were significantly higher in the tyne compared with the disc (80 vs 50 plants/m² respectively, P<0.05 - Figure 11). Greater early vigour by the tyne (Figure 12) allowed better recovery from early locust damage.

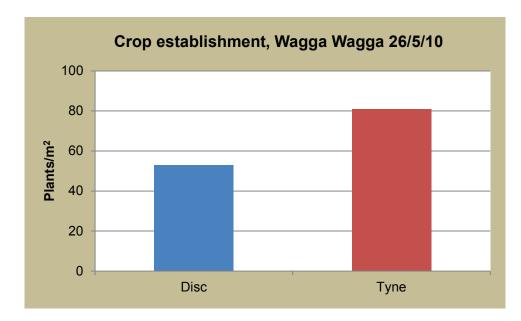

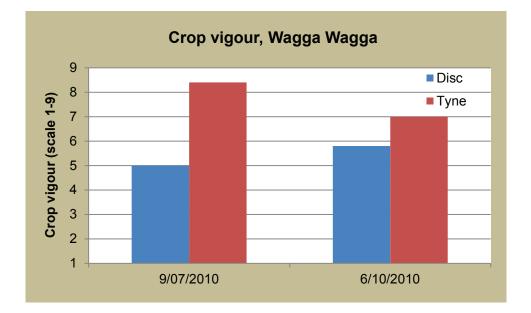

Figure 11 - Crop establishment disc versus tyne, Wagga Wagga (LSD P<0.05 = 5)

Figure 12 - Crop vigour disc versus tyne, Wagga Wagga (LSD P<0.05 = 0.4 9th Jul; = 0.5 6th Oct)

• Weed control: In the presence of very high weed numbers, weed control appeared better in the tyne treatments three months after application (significant at P<0.05), but this difference was not apparent later in the season (Figure 13).

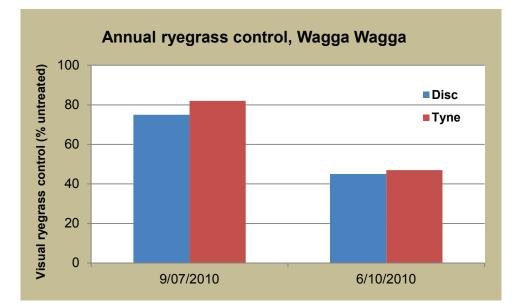

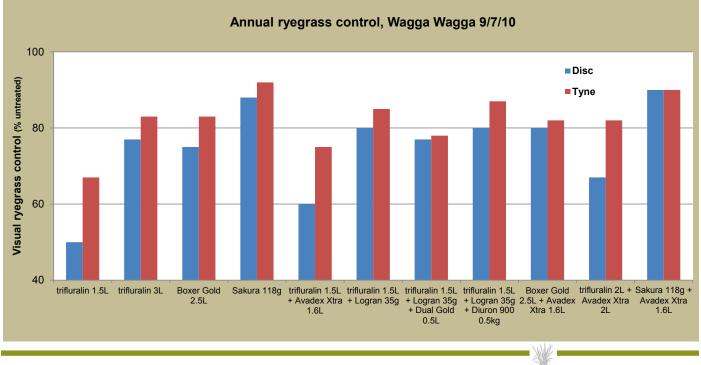

Figure 13 - Annual ryegrass control disc versus tyne, Wagga Wagga (LSD P<0.05 = 3 9th Jul; = 4 6th Oct)

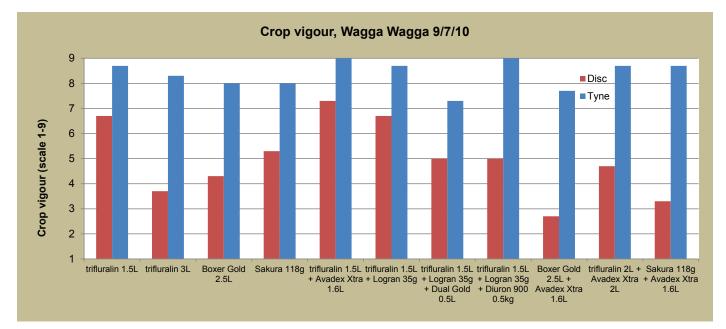

Sakura provided the best weed control for both systems. This was evident both mid-season (Figure 14), as well as later in the season when its residual activity provided excellent control of later germinating ryegrass populations resulting from the favourable season. The 1.5L rate of trifluralin provided the poorest ryegrass control, which was significantly improved at the 3L rate or with tank mixes including Logran, Dual Gold, Avadex Xtra and Diuron (P<0.05 - Figure 14).

Figure 14 - Annual ryegrass control herbicide comparison, Wagga Wagga (LSD P<0.05 = 9)

 Crop safety: The impact of certain pre-emergent herbicides on crop safety was far more evident in the disc system than the tyne (Figure 15). Crop damage in the disc treatments was greatest with Boxer Gold + Avadex Xtra, although not significantly worse than Sakura + Avadex Xtra or 3L/ha trifluralin (P>0.05).

The Wagga Wagga trial was spray fallowed in October to prevent seed set of heavy populations of annual ryegrass, October 2010

Discussion of Results

Tyne seeding systems using knife points and press wheels are well recognised for their ability to accurately place seed at consistent depths across a range of soil types. Trial results from this project have shown they can also exceed disc seeding systems in crop establishment and early vigour when sowing conditions are favourable. However zero-till seeding using disc openers and full stubble retention is generating significant interest to further improve the gains made in no-till farming. Disc seeding allows higher sowing speeds and consistent seed placement into marginal soil moisture in the presence of stubbles, which in drier seasons, has achieved yield advantages over tyne systems, and often equal yields in more favourable seasons.

Crop Safety

No-till type systems have been rapidly adopted by growers in recent years, partly due to greater confidence in the use of pre-emergent herbicides. Growers and advisers now better understand the impact variations in sowing speed, row spacing and soil throw can have on herbicide efficacy. Label registrations also reflect this level of understanding, with the majority of pre-emergent herbicides now registered for use in no-till seeding systems using a knife point and press wheel.

While interest in disc seeders has also increased rapidly, aspects of the disc system need to be further investigated before widespread adoption occurs to ensure critical areas such as herbicide efficacy and yield are not compromised. The trials outlined in this report highlight the variability in crop safety that can occur with disc seeding in no-till systems when pre-emergent herbicides are incorporated by sowing (IBS), ranging from little crop damage at the drier Lockhart site to significantly greater damage at the waterlogged Grenfell site.

The trials were undertaken with commercial seeding equipment sown at typical speeds and sowing depths, and highlight the relative safety of using pre-emergent herbicides in type systems compared with discs. However the wet conditions at the Grenfell site served as an important reminder that some herbicides and higher rates can still be damaging in type systems. While the majority of pre-emergent herbicides are mobile when used in wet soils, some cause more crop damage in cereals than others due to greater mobility. Crops that are stressed during establishment due to waterlogging, poor nutrition or slow emergence (eg. from disc seeding) are put under greater pressure from pre-emergent herbicides and the industry needs to be aware of the variability that can occur.

To ensure crop damage is minimised across a range of soils and seasonal conditions, soil treated with residual pre-emergent herbicides needs to be removed from the furrow during seeding by soil throw. The ability to shift soil varies between disc seeders, with features such as row cleaners ahead of the single disc helping to reduce crop damage. Other factors, including disc size, disc shape, disc angle, closer plates and sowing speed all impact upon soil throw and the quantity of treated soil falling back into the seed furrow.

Weed Control

Despite significant differences in crop safety between disc and tyne systems, there was little difference in weed control between the two systems. This is a surprising result and may be particular to the unusually wet season. Pre-emergent weed control is typically more effective in tyne systems where additional soil throw results in better herbicide incorporation, although disc seeder adaptations such as Aricks residue managers have the potential to improve this aspect.

Discussion of Results cont.

Although there were no obvious differences in weed control between the sowing systems, there were variations in weed control between the pre-emergent herbicides treatments. For example, the low rate of trifluralin at 1.5L/ha, which has been commonly used as a pre-emergent herbicide strategy, was significantly less effective than all other herbicide treatments at the Wagga Wagga site, but not at Grenfell. However at both sites, Sakura used alone and in a tank mix with Avadex Xtra gave consistently high levels of ryegrass control. Boxer Gold also performed well at the Grenfell site, but was not as effective as some other herbicide treatments at Wagga Wagga. Sakura is expected to be available for the 2012 season.

Implications

The adoption of no-till seeding systems in southern NSW has increased rapidly over recent years as growers seek the benefits of increased water use efficiency. However it is important that the level of agronomy associated with these systems 'keeps pace' to ensure optimum and sustainable performance. The outcomes from this project have been significant in alerting growers, advisers and chemical company representatives of the extra diligence required to manage pre-emergent herbicide use in no-till systems, particularly where a disc seeder is used. The unusually wet season in 2010 further highlighted the issue, with many growers who had adopted disc seeding during the recent run of dry seasons unaware of the crop damage that can occur in wet conditions.

Manufacturers are already making adaptations to suit single disc openers that aim to throw more soil for improved herbicide safety with soil shifting row cleaners (eg. Tobin disc drill), seed boot shields with built in soil deflectors (eg. Daybreak) and a reversible and adjustable disc closer (eg. NDF Ag Design). The use of ground driven residue managers (eg. Aricks wheels) to displace soil and stubble from the seeding row is also being investigated for additional soil throw in pre-emergent herbicide use.

Although the project was invaluable in highlighting the risks associated with pre-emergent herbicide use in no-till systems, particularly disc systems, the major outcome of the project was that successful pre-emergent weed control can be achieved with minimal soil disturbance. Awareness of machinery configurations or adaptations to increase soil throw, as well as an understanding of the increased mobility of some herbicides and/or high rates in wet conditions, will help growers and advisers maximise herbicide efficacy in no-till systems. However this can only be achieved if herbicide use is managed as part of of an integrated weed management system. Keeping weed numbers low is critical in no-till situations, so a combination of chemical and cultural techniques such as burning canola header trails, cutting for hay/silage or header additions that destroy weed seeds at harvest, should be utilised to ensure sustainability of the system.

Recommendations

To further enhance the outcomes from the project, it is recommended that additional investment be made into comparing the performance of machinery adaptations designed to remove herbicide treated soil from the furrow in both disc and tyne systems, under different soil moisture conditions.

It is also recommended that greater awareness be made of the potential crop damage that can occur with the use of pre-emergent herbicides in wet conditions, particularly when incorporated with a disc seeder.

Herbicide Efficacy in No-Till Farming

Assessing the herbicide efficacy of various preemergent herbicides in disc and tyne sowing sytems. (Grassroots Agronomy, AgriTech NSW, FarmLink; funded by GRDC, with support from Bayer, Nufarm & Syngenta)

2010 Trials

- A new project led by Grassroots Agronomy, funded through GRDC's Southern Agribusiness Trial Network.
- The project aims to demonstrate the differences (eg. crop safety and weed control) between a range of pre-emergent herbicides and how they compare in both disc and tyne sowing systems.
- 3 sites: Downside, Grenfell, Lockhart.

► Trial details:

- » Large scale plots are to be sown using farmer machinery in autumn 2010 (Downside sown in April - Figures 8 & 9).
- » Replicated pre-emergent herbicide treatments (Table 2) are applied by AgriTech prior to sowing using a six metre boom (Figure 7). All treatments are incorporated by sowing (IBS).
- » Each site will target one of the major weed issues in the region including resistant annual ryegrass, wild oats and mixed populations of annual grasses.
- » Monitoring will be undertaken during the season to assess herbicide efficacy (post sowing and post harvest), crop growth, yield, quality and gross margins.

Grenfell 'farmwalk' - Friday, 23rd July 2010

- Aim: To assess any differences in crop safety and weed control between a range of pre-emergent herbicides in disc and tyne sowing systems.
- Sown: 20th May 2010 using Daybreak disc and Horwood Bagshaw tyne seeders.
- Treatments: Herbicides applied by AgriTech 20th May (IBS) using six-metre boom, as follows:

| Table 1 - Herbicide Efficacy Trial Treatments, 2010 | | | | | | | | | |
|--|--------------------|--|--|--|--|--|--|--|--|
| Herbicides | Rates/ha | | | | | | | | |
| Triflur X ¹ | 1.5L | | | | | | | | |
| Triflur X ¹ | 3L | | | | | | | | |
| Boxer Gold ¹ | 2.5L | | | | | | | | |
| Boxer Gold ¹ + Avadex Xtra | 2.5L + 1.6L | | | | | | | | |
| Sakura ² | 118g | | | | | | | | |
| Sakura ² + Avadex Xtra | 118g + 1.6L | | | | | | | | |
| Triflur X ¹ + Avadex Xtra | 1.5L + 1.6L | | | | | | | | |
| Triflur X ¹ + Avadex Xtra | 2L + 2L | | | | | | | | |
| Triflur X1 + Logran | 1.5L + 35g | | | | | | | | |
| Triflur X ¹ + Logran + Dual Gold ³ | 1.5L + 35g + 500mL | | | | | | | | |
| Triflur X ¹ + Logran + Diuron ³ | 1.5L + 35g + 500g | | | | | | | | |
| control: untreated buffers | | | | | | | | | |

not registered for IBS with disc seeders

²registration pending (due 2011); ³not registered for IBS in wheat in NSW

Results to date:

- » *Disc v tyne (Figures 1-3):* Tyne machine better establishment and early vigour, but more ryegrass (relatively low pressure).
- » *Crop safety (Figures 4-5):* Some herbicides impacted on crop vigour with tyne machine, but all less impact than disc machine.
- » *Weed control:* No significant difference in ryegrass numbers between herbicide treatments. Visual ryegrass control still to be assessed.

Project collaborators:

Grassroots Agronomy

FarmLink

Figure 1

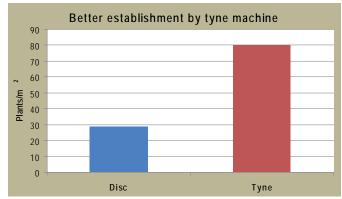

Figure 2

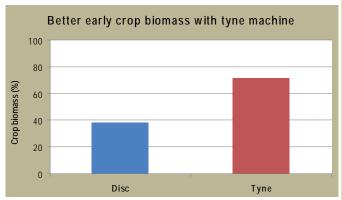

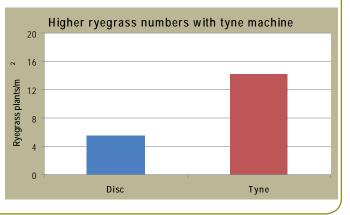

Figure 3

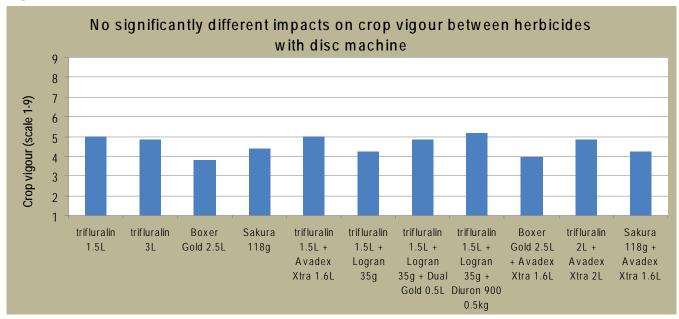

Project funded by:

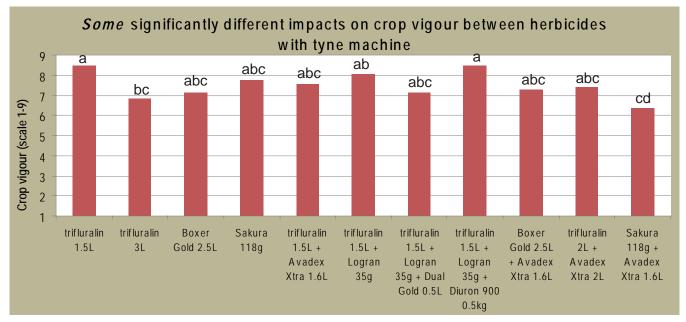

Grains Research & Development Corporation

Figure 4

All herbicides in the disc area had a similar impact on crop vigour, but all had significantly lower vigour than the tyne area.

Figure 5

Results with the same letter(s) are not significantly different, eg. trifluralin at 3L/ha had a significantly greater impact on crop vigour in the tyne area than the 1.5L/ha rate, alone or with Logran + diuron, but was not significantly different to the remaining treatments.

Herbicide Efficacy in No-till Farming Systems in Southern NSW

Greg Condon and Kirrily Condon, Grassroots Agronomy, Junee, NSW

Key Words

No-till farming systems, zero-till, weed management, pre-emergent herbicides, disc seeding, tyne seeding

Take home messages

- Disc seeding into wet soil in the presence of residual pre-emergent herbicides caused a severe reduction in wheat crop vigour compared with the type seeder.
- Tyne seeding resulted in consistently better establishment and early vigour than disc seeding, but weed control was generally similar for both systems.
- Under very high ryegrass pressure, Sakura provided significantly better weed control through to late spring in both disc and tyne systems. Boxer Gold and trifluralin mixes provided good to moderate ryegrass control compared to a low rate of trifluralin used alone.
- Weed management in no-till systems, especially where a disc opener is used, requires a high level of agronomic management to maintain crop safety and achieve satisfactory weed control. The majority of pre-emergent herbicides used in wheat are not currently registered for use with disc seeders*.

Variable rainfall patterns over the past ten years in southern NSW have prompted the rapid adoption of no-till, stubble retained farming systems to maximise crop water use efficiency. Despite the many benefits of this system, the efficacy of pre-emergent herbicides remains one of the major concerns for growers and advisers who have adopted, or are considering adoption, of the system.

The problem

Pre-emergent herbicides play an important role in integrated weed management programs as they allow for rotation away from high risk Group A and B herbicides. However, poor efficacy of pre-emergent herbicides can still result in the rapid development of herbicide resistance, as has occurred with trifluralin resistance that is common in South Australia.

The efficacy of many pre-emergent herbicides relies on the ability to incorporate them into the soil at sowing. In no-till systems, however, knife points and to a greater extent, disc openers, provide minimal soil disturbance at sowing to limit moisture loss, but which consequently also limit herbicide incorporation. Retained stubble also acts as a physical barrier to herbicide/soil contact. This issue is further confounded where livestock are included in the system, with stubble laid flat from trampling providing a physical barrier to herbicide uptake. Effective pre-emergent herbicide strategies are required to ensure the future sustainability of both herbicides and no-till farming systems.

Finding the solution

To help develop pre-emergent herbicide strategies relevant to no-till farming systems in southern NSW, a local consortium was funded by GRDC to implement three trial sites in 2010 comparing herbicide efficacy in disc and tyne (knife point) systems (Table 1). The sites were located near Grenfell, Wagga Wagga and Lockhart, with commercial machinery used to sow large scale, replicated plots at typical speeds to ensure soil throw and accurate seed placement. Preemergent herbicide treatments (Table 2) were applied by AgriTech using a six-metre boom and incorporated by sowing (IBS).

¹ **not** registered for IBS with disc seeders ² registration pending (due 2012)

³ **not** registered for IBS in wheat in NSW

*Caution: Research on unregistered pesticide use. Any research with unregistered products reported in this document does not constitute a recommendation for that particular use by the authors or the author's organisation. All pesticide applications must accord with the currently registered label for that particular pesticide, crop, pest and region.

Results

Although different outcomes were achieved at each site due to variations in weed density, soil moisture and stubble loads, the type seeder produced consistently better establishment and early crop vigour at all sites. A summary of the other major outcomes are as follows:

Wagga Wagga

- Site conditions: Wedgetail wheat was sown early into good moisture and 50% stubble cover. Very high ryegrass numbers (up to 190 plants/m²) with low crop competition due to early locust damage represented an extreme scenario to test pre-emergent herbicide efficacy.
- Emergence: Plant numbers were significantly higher in the type compared with the disc (80 vs 50 plants/m² respectively, P<0.05). Greater early vigour by the type allowed better recovery from early locust damage.
- Weed control: There was little difference in ryegrass control between disc and tyne, with Sakura providing the best control for both systems. Boxer Gold, trifluralin at 3L/ha and trifluralin mixes with Logran, Dual Gold, Avadex Xtra and Diuron all provided significantly higher levels of control than trifluralin at 1.5L/ha (P<0.05, Figure 1). Sakura also provided

excellent residual control of ryegrass for later germinating populations resulting from the favourable season.

- Crop safety: The impact of certain pre-emergent herbicides on crop safety was far more evident in the disc system than the tyne. Crop damage in the disc treatments was greatest with Boxer Gold + Avadex Xtra, although not significantly worse than Sakura + Avadex Xtra or 3L/ha trifluralin (P>0.05).
- To ensure crop damage is minimised across a range of soils and seasonal conditions, soil treated with residual pre-emergent herbicides needs to be removed from the furrow during seeding by soil throw. The single disc openers used in this trial were unable to fully achieve this objective. The ability to shift soil does vary between disc seeders, with features such as row cleaners ahead of the single disc helping to reduce crop damage. Other factors, including disc size, disc shape, disc angle, closer plates and sowing speed all impact upon soil throw and the quantity of treated soil falling back into the seed furrow.

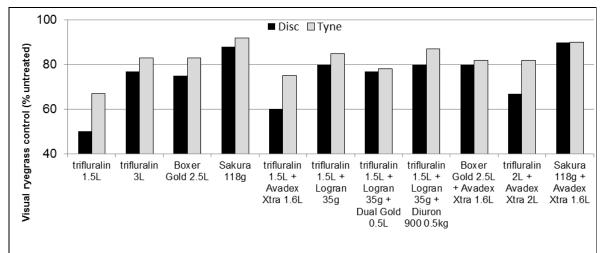

Figure 1 – Ryegrass control in disc and tyne systems at Wagga Wagga; LSD (0.05) = 9

Lockhart

- Site conditions: Lincoln wheat was sown mid-May into dry conditions and patchy stubble cover from an uneven burn. Very low ryegrass and wild oat numbers meant the trial could be retained through to harvest, allowing a valid comparison of disc and tyne systems in the relative absence of weeds.
- Emergence: Plant numbers were significantly higher in the tyne compared with the disc (120 vs 80 plants/m² respectively, P<0.05), with disc emergence more affected by the presence of stubble and sowing across the seeding rows from the previous year. Greater early vigour by the tyne became less apparent as the season progressed.
- Crop safety: Conditions remained dry for approximately one month after the trial was established, which reduced damage from residual herbicides on the emerging crop. Crop safety was, however, compromised with 3L/ha trifluralin in the disc treatment, resulting in lower vigour and yield, although not significantly lower than other treatments (P>0.05).
- Yield: There were no significant yield differences between the disc and tyne treatments (P>0.05), a reflection of the drier nature of the site and subsequent improved crop safety with pre-emergent herbicides.

Grenfell

- Site conditions: Livingston wheat was sown into moist soil and a thick residue of stubble retained from previous wheat crops. Following establishment, approximately 50mm of rain fell onto an already full profile, which remained wet for the entire season. 1015mm of rainfall was measured for the area in 2010, with 650mm falling between September and December. The wet conditions had a major bearing upon outcomes from this trial, particularly the disc treatments which suffered from poor establishment and severe herbicide damage.
- Establishment: Plant numbers were significantly higher in the tyne compared with the disc (80 vs 30 plants/m² respectively, P<0.05). Crop vigour was also better in the tyne treatments, which remained the case through the season. As the soil became wetter during winter, the disc area was unable to recover its vigour due to a range of factors including herbicide damage, yellow leaf spot, nitrogen deficiency and waterlogging.
- Weed control: Low to moderate ryegrass numbers were present at establishment, with similar levels of control between the disc and tyne treatments. 1.5L/ha trifluralin + Logran gave the poorest control for both systems, although it wasn't significantly worse than some other treatments (P>0.05). With low crop competition, particularly in the disc treatments, and later germinations of ryegrass, the trial became heavily infested and was spray fallowed in October to prevent seed set.
- Crop safety: Herbicide damage in the disc areas was particularly evident at this site, with the majority of herbicide treatments causing significantly more crop damage than 1.5L/ha trifluralin (P<0.05), which recorded the least damage (Figure 2). Yield estimates taken prior to spray fallowing showed the disc treatments to potentially average 0.36t/ha and the tyne treatments 1.0t/ha, with a range across all treatments of 0.15 to 1.37t/ha depending on herbicide, seeding system and weed control.
- Despite the wet season, these yields are well below profitable targets for wheat in this
 region and highlight the risks associated with using pre-emergent herbicides at robust
 rates in no-till systems. The majority of pre-emergent herbicides are mobile when used in
 wet soils, with some causing more crop damage in cereals than others due to their
 mobility. Crops that are stressed during establishment due to waterlogging, poor nutrition
 or slower emergence from disc systems are put under greater pressure from preemergent herbicides and the industry needs to be aware of the variability that can occur.

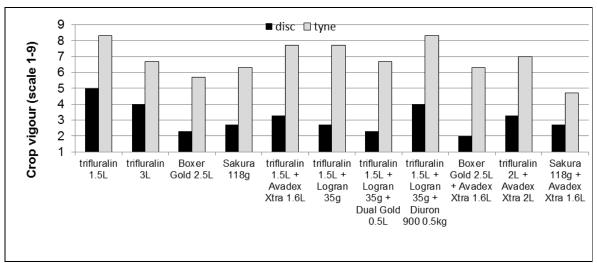

Figure 2 – Crop safety in disc and tyne systems at Grenfell; LSD (0.05) = 2.2

Discussion

No-till farming utilising sound agronomy is a proven system of crop management that reduces production risk through improved soil structure, enhanced water use efficiency and ultimately stable profits for growers. Knife point and press wheel seeding systems are now well understood for their ability to accurately place seed at consistent depths across a range of soil types in the presence of pre-emergent herbicides. Awareness of differences achieved through variations in sowing speed, row spacing and soil throw are better understood by growers and consequently there is greater confidence with using pre-emergent herbicides in no-till systems. Label registrations now reflect this level of understanding, with the majority of pre-emergent herbicides now registered for use in no-till seeding systems using a knife point and press wheel.

Developments such as full stubble retention and zero-till seeding with discs are now being investigated for their value to further improve the gains made in no-till farming. Disc seeding allows higher sowing speeds and consistent seed placement into marginal soil moisture in the presence of stubbles, which in drier seasons, has achieved yield advantages over tyne systems.

Before these developments are widely adopted, aspects of the disc system need to be further investigated to ensure standards are maintained with key areas such as weed management and yield. The trials outlined in this report highlight the variability that can occur with disc seeding systems in no-till when pre-emergent herbicides are incorporated by sowing (IBS), ranging from little crop damage at the drier Lockhart site to significantly greater damage in the disc treatments at the waterlogged Grenfell site.

Growers and advisers will continue to improve on the no-till system in relation to crop safety with pre-emergent herbicides, particularly using disc seeding technology. Manufacturers are already making adaptations to suit single disc openers that aim to throw more soil for improved herbicide safety with soil shifting row cleaners (eg Tobin disc drill), seed boot shields with built in soil deflectors (eg Daybreak) and a reversible and adjustable disc closer (NDF Ag Design). The use of ground driven residue managers (eg Aricks wheels) to displace soil and stubble from the seeding row is also being investigated for soil throw and pre-emergent herbicide use.

Further improvements to the no-till system, particularly in relation to canopy management in disc and tyne systems, is being investigated in another GRDC funded project in 2011.

- 300mm row spacing
- Disc
- John Deere single disc
- · 250mm row spacing

Wagga Wagga

- 50% stubble cover, locusts, early sown
- · High ryegrass numbers, up to 190 plants/m² (fallowed in spring)
- Plant numbers higher in tyne 80 vs 50 plants/m²
- Weed control no difference between disc and tyne, high pressure site weakest product 1.5L Triflur, residual with Sakura
- Crop safety damage in disc

- Horwood Bagshaw Ryan press harrows
- 350mm row spacing
- · Daybreak disc
- · 375mm row spacing

Lockhart

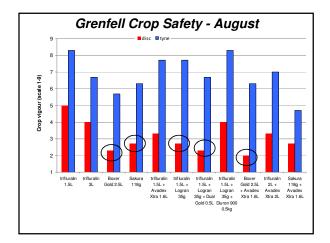

- Dry site at sowing, patchy burn
- Wet in winter/spring after establishment
- · Low weed pressure
- · Plant numbers higher in tyne 120 vs 80 plants/m²
- Crop safety excellent, but 3L Triflur in disc
- Yield no significant difference between disc or tyne 3.2t/ha versus 3.3t/ha

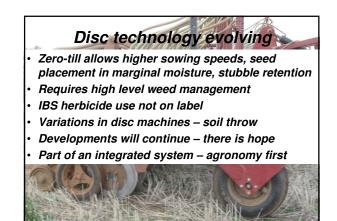

Results 3 sites achieved different outcomes due to: Weed density Soil moisture Stubble loads

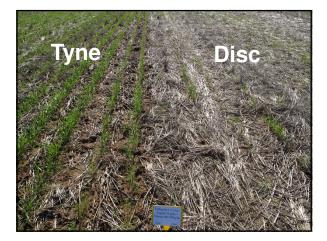

Tyne seeder produced consistently better establishment and early crop vigour yet...

Grenfell

- Sown into thick residue, wet soil
- Rainfall1015mm for year, 650mm Sep-Dec
- Moderate weed pressure (fallowed)
- Low plant numbers yet still higher in tyne 80 vs 30 plants/m²
- Disc area unable to recover during spring
- Weed control equal between disc & tyne
- Severe crop damage across all herbicides
- Low potential yield combination of issues
